16 **Abstract**

17 Eight Midwestern states united in creating a first-of-its-kind Regional Truck Parking Information  
18 Management System (TPIMS) to reduce the incidence of commercial truck drivers injuring themselves  
19 and other drivers due to fatigue-related crashes and unauthorized parking along the interstate highways.  
20 The core ITS technologies used for the system are not complex - monitoring available parking at  
21 authorized public and private truck facilities in real time, and then relaying the information to truck  
22 drivers and dispatchers through roadside dynamic truck parking signs (DTPS), mobile applications and  
23 state traveler information websites such as 5-1-1. However, deployment of a regional project across  
24 multiple agencies and state lines is complex, no more so than in the need to accommodate the  
25 organizational policy and technology needs and preferences of the eight partner states (Indiana; Iowa;  
26 Kentucky; Michigan; Minnesota; Ohio; Wisconsin; and Kansas, the lead agency for the \$25 million  
27 federal TIGER grant which underwrites much of the initiative). This paper explores the lessons learned  
28 in developing and implementing a complex, multi-jurisdictional technology initiative as it nears full  
29 operational status in January 2019 and begins producing results that expect to reduce crashes while  
30 improving the efficiency and profitability of the regional freight system. It also highlights how those  
31 lessons can be more broadly applied to major multi-jurisdictional transportation projects of all kinds.

32 **Keywords:** ITS, Freight, Truck Parking, Technology

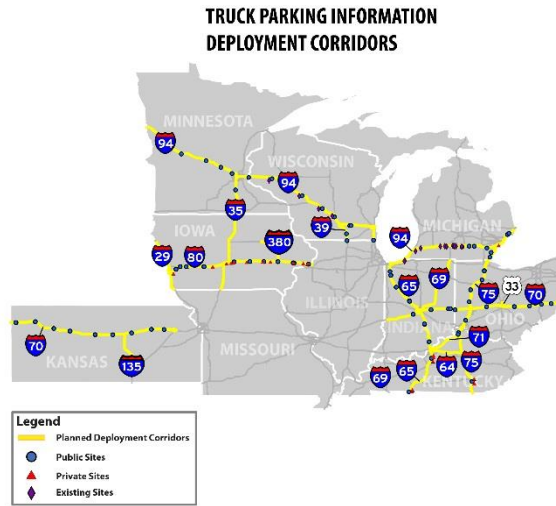

1 **Introduction**

2 Safe, convenient parking is essential for long-haul truck drivers, the lifeblood of the U.S. freight  
3 transportation network. Yet many drivers often struggle for up to an hour each day to find areas to safely  
4 rest - putting themselves and other drivers at risk when searching while fatigued. (1)

5 That’s why eight states – Indiana, Iowa, Kansas, Kentucky, Michigan, Minnesota, Ohio and Wisconsin –  
6 joined together to develop a real-time, multi-state Truck Parking Information Management System  
7 (TPIMS). (2)

**Figure 1: TPIMS Geographical Reach**

8 When fully operational in January 2019,  
9 TPIMS will improve the safety and  
10 efficiency of America’s freight network  
11 by providing real-time parking  
12 availability information to truck drivers  
13 through dynamic message signs, smart  
14 phone applications, traveler information  
15 websites and other means.

16 This regional system will enable truck  
17 drivers, dispatchers and others to see and  
18 benefit from a consistent, cohesive  
19 parking availability system that crosses  
20 state lines, benefitting regional and  
21 national freight movements.

*TPIMS is being deployed along the region’s high-volume freight corridors using existing ITS infrastructure and emerging vehicle detection and data collection technologies. Locations were selected based on factors such as trucking volume, parking demand and site capacity for improvements.*

22 The planning, design and deployment of  
23 TPIMS followed the systems engineering  
24 process. An appropriate level of up front  
25 planning and documentation was completed to  
26 insure stakeholder needs were met in a manner  
27 that can be efficiently implemented and  
28 operated by each state.

29 In the process, TPIMS also provides important lessons for successfully developing and delivering  
30 complex, multi-jurisdictional technology projects of all types while integrating individual and collective  
31 agency goals and needs.

32 **Addressing regional problems through technology**

33 The MAASTO Regional TPIMS initiative was established in recognition that commercial trucks move  
34 nearly two-thirds of North America’s almost \$1.2 trillion in freight shipments annually. (3) How and  
35 when these long-haul truck drivers will find safe spots to rest are logistical details often overlooked,  
36 however. That’s why truck drivers consistently report issues finding safe, legal parking places along their  
37 routes. In one study conducted for the Kansas Department of Transportation (KDOT), 78 percent of  
38 drivers reported that on average it takes them longer than 30 minutes to find parking. (4)

1 The longer a fatigued truck driver is on the road looking for a spot to park, the higher the risk of a crash  
2 happening. Eighty-five percent of truck drivers surveyed said that they occasionally or regularly found  
3 themselves fatigued while driving and had an unsafe feeling because they were not able to find safe truck  
4 parking. (5) When fatigued, drivers cannot find legal spots to park, they often park on freeway ramps or  
5 in unauthorized lots, putting at risk themselves and other motorists.

6 Having identified the issue, the TPIMS partner states (Partnership) developed and agreed to a set of goals  
7 for the initiative based on multilateral discussions, availability and robustness of data and collection  
8 methods to underpin performance measurements, and other factors. The project goals that emerged  
9 included:

- 10 1. Improve safety
  - 11 a. Reduce crashes (fatigue related)
  - 12 b. Reduce illegal/informal parking on ramps
  - 13 c. Improve personal safety and security for  
14 commercial drivers
- 15 2. Provide timely, reliable and accurate truck parking  
16 availability information
- 17 3. Provide harmonious and consistent operations between  
18 states
  - 19 a. Regional consistency and branding
  - 20 b. Seamless across state lines
  - 21 c. Universal data interface (API) with private  
22 industry helping to provide innovations for data  
23 dissemination
- 24 4. Maximize usage of existing parking assets
- 25 5. Add value to the trucking industry
- 26 6. Implement in a sustainable way
  - 27 a. Show return on investment with clear, measurable  
28 public benefit
  - 29 b. Mitigate long-term O&M costs – potential  
30 transition of system to private industry or others
- 31 7. Allow some state-specific flexibility (procurement and  
32 truck parking monitoring technologies)

33 Such a commitment to a common approach can be  
34 challenging for cross-jurisdictional technology projects.

35 Partner agencies typically will have a broad range of options to consider when they undertake a  
36 technology-related initiative. Narrowing the potential options is made significantly easier when research  
37 springs from clear project goals and quantifiable performance measures.

38

**Figure 2: Lesson 1**

**FOCUS ON OUTCOMES**

Focusing on outcomes – safety, ease of use, consistent regional access to parking information – was critical for success. Agreed-to goals enabled the Partnership to reframe discussions about technological solutions in terms of end-user benefits rather than agency custom. It mooted potential conflicts about how each state delivered those benefits since each one could achieve the goal in its own way, reflecting its operational, regulatory and statutory preferences and constraints.

2 *Successfully completing regional technological initiatives may necessitate reconciling different, perhaps conflicting, agency technical preferences and requirements as seen in this Core Functions Matrix. These can be deeply embedded in an individual agency’s business rules or typical practice. The Matrix provided a way for participant agencies to better visualize where conflicts and commonalities might arise during TPIMS planning.*

3 Development of the project’s core functions, represented in the figure, are discussed further below.

4 **Defining end user needs and expectations**

5 A powerful tool for further refining choices a technology partnership must make involves being very clear  
6 about expectations and requirements of internal and external end users. This helps strengthen the project  
7 team’s understanding of the opportunities and limitations of each technology being considered for a given  
8 task.

9 The TPIMS partners did considerable internal and external outreach to improve the proposed system and  
10 mitigate or eliminate potential threats to project success. This engagement involved a mix of workshops,  
11 surveys and face-to-face meetings conducted throughout the implementation region.

12 By engaging with trucking associations, for example, the Partnership could identify when drivers start  
13 planning where to park and, by extension, where TPIMS signage and marketing needed to occur. It also  
14 underscored the importance of providing parking information electronically through smart phone  
15 applications or in-cab navigation systems that are increasingly the hub through which drivers make and  
16 document their driving decisions. Meanwhile, external end users had expectations and statutory  
17 requirements that necessitated delivering accurate, real-time parking information in an electronic format,  
18 regardless of other delivery methods used. Finding a technology solution that could satisfy all these  
19 requirements helped rapidly narrow the field of potential answers.

20 As a result, the partnership reached out third-party application developers such as Google, Waze and  
21 Truck Specialized Parking Services, among others, to engage them in using TPIMS parking data in their  
22 apps.

1 To help measure whether this goal would be achieved, the TPIMS Partnership developed three broad  
2 categories of performance measures:

- 3 1. Parking utilization and demand involves measuring driver perceptions of how full MAASTO truck  
4 stops are and how often. Parking utilization and demand cycle data will be collected through system  
5 statistics as well as yearly through a driver survey conducted by the American Transportation  
6 Research Institute (ATRI).
- 7 2. Corridor safety reflects the number of fatigue-related crashes on TPIMS corridors. Corridor safety  
8 data - including fatigue-related truck crash rates, types and patterns - will be analyzed and reported by  
9 the Mid-America Freight Coalition  
10 (MAFC).
- 11 3. System reliability will show how well the  
12 system is operating. System reliability  
13 will be measured by total system  
14 downtime, number of user complaints and  
15 the difference in the number of spots that  
16 the system says are open and that are  
17 available.

**Figure 3: Lesson 2**

### LINK GOALS AND PERFORMANCE

The ability to rule particular technology in or out of consideration based on agreed-to goals and performance measures reduces opportunities for delay.

It shifts the focus from “how we do it” to “will it help achieve the end results.” In the process, partner agencies can better accept differing agency approaches if they see they don’t affect the ultimate delivery of services and results.

Finally, it is simpler to address late-breaking project questions or changes by analyzing them in light of whether they improve or degrade results under agreed-upon performance measures.

### **Innovative technologies for building a safer network**

20 Thoroughly understanding end user needs  
21 coupled with well-articulated actionable and  
22 measurable goals helped simplify decisions  
23 underpinning three important categories of  
24 technology deployment that make TPIMS  
25 possible:

- 26 • Detection of available parking
- 27 • Collection and storage of parking  
28 availability data and
- 29 • Communication of parking data to  
30 drivers

### Detection of available parking

32 The number of designated spots differs facility to facility, and there are many ways to count the number  
33 of spots occupied or available. The level of vehicle detection accuracy and how availability level is  
34 communicated are critical for DOTs to build trust among truck drivers such that they can rely on using the  
35 system to make productive routing and parking decisions. A TPIMS baseline survey had revealed that  
36 system reliability is the most important concern for truck drivers followed closely by system accuracy.  
37 Therefore, the Partnership created performance standards to monitor both. For example, small parking  
38 facilities (less than 15 spots) will need to meet an 85% accuracy threshold. A 90% threshold will be the  
39 benchmark for large parking facilities (15 or greater spots).

1 Having agreed to performance measures and a commitment to end user needs enabled the Partnership to  
2 identify and deploy two different methodologies for monitoring available parking that best fit agency and  
3 local user needs. The two approaches involved counting flows in and out of a truck parking area or  
4 detecting space occupancy.

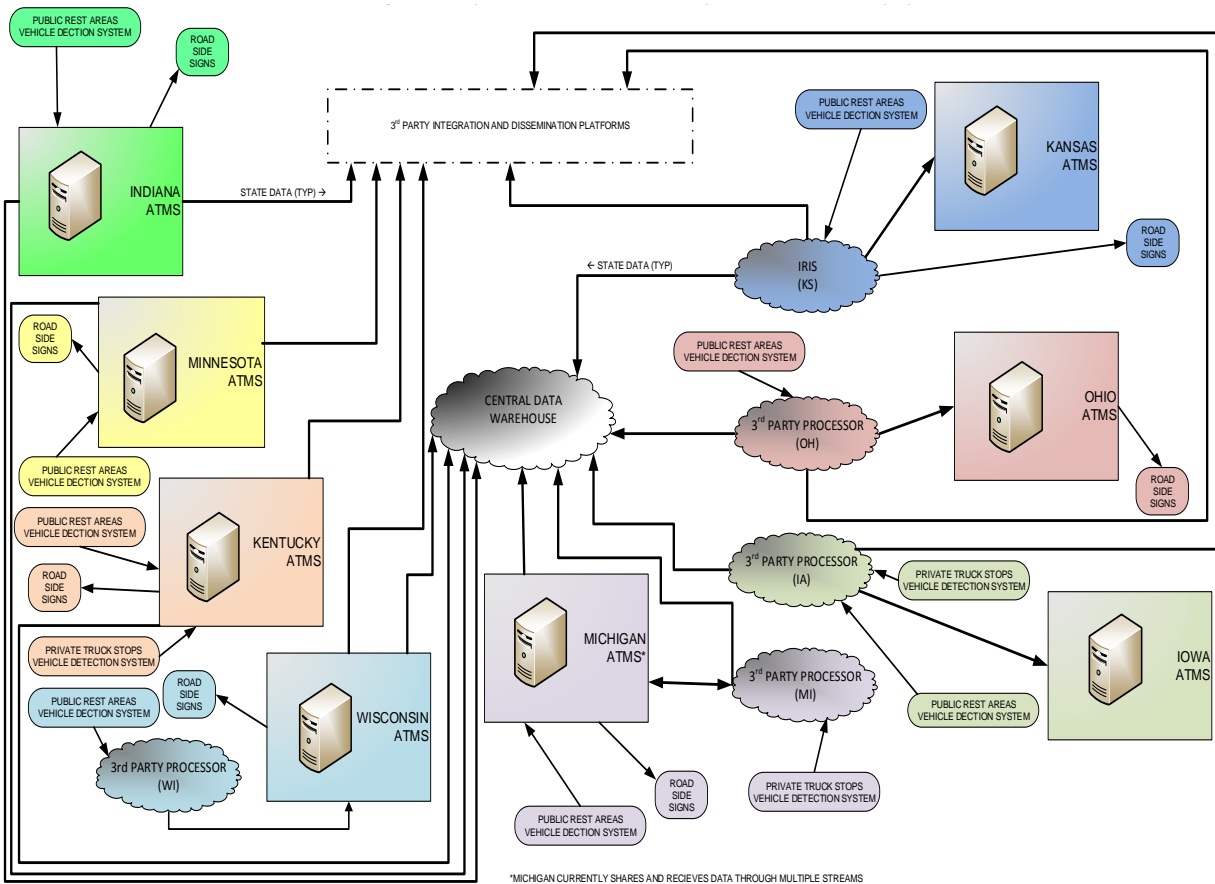

5 Several Partnership states have chosen to use the “one in and one out” method for estimating available  
6 spots. This method requires a parking facility with designated entrances and exits. When a truck enters a  
7 facility, the system is triggered to account for one less spot. Likewise, when a truck exits the parking  
8 facility the system refreshes to reflect another parking spot becoming available. The benefit of this  
9 methodology is cost effectiveness for larger parking areas and the ability to accommodate informal  
10 parking beyond marked parking spaces. The downside is that truck counting errors can accrue until  
11 manually corrected, so the available space count must be verified and reset by operators regularly and  
12 periodically. With this methodology, either magnetometer-based sensors or video detection is being used  
13 to count trucks entering and exiting parking areas.

14 The second methodology senses vehicle occupancy in defined parking spots to determine how many  
15 spaces are being used. Two different technologies will be used to monitor parking stall occupancy – video  
16 analytics and wireless magnetometer sensors in the pavement. Both technologies determine if a defined  
17 parking stall is occupied. This methodology requires less effort to monitor and correct inaccuracies  
18 because trucks are only counted when they occupy or leave parking slots in a manner sufficient to trigger  
19 sensors. Thus, errors are “reset” when the vehicles move and do not accrue over time. However, since  
20 each parking stall must be monitored, the cost increases as the number of spaces increases. This  
21 methodology also cannot adapt as easily to informal parking and when vehicles park in undefined spaces,  
22 such as when snow covers the ground.

### 23 Collection and storage of parking availability data

24 The TPIMS Partnership states will collect and send their data to a central data warehouse operated by the  
25 Mid-America Freight Coalition. From there it will be provided to other partner states and third-party  
26 vendors for use. Each state will determine how it will collect and transmit its data within the common  
27 standards the Partnership created to promote interoperability across state lines. The result is that users of  
28 the system will see no difference in how it operates from state to state, despite each state taking a different  
29 path towards integrating its parking information efforts with its existing ITS network and software  
30 platforms and vendors.

**Figure 4: TPIMS Data Collection and Storage**

1

*A commitment to a common user experience means that they will see no difference in how the system operates from state to state, despite each state taking a different path towards integrating its parking information efforts with its existing ITS network and software platforms and vendors.*

2 Communication of parking data to drivers

3 Websites, mobile applications and DTPS will provide truck parking data to truck drivers. Dynamic  
 4 messaging signs will include information on where the truck parking facility is located and how many  
 5 spots are available. Parking information for up to three of the nearest parking facilities will be displayed  
 6 on each DTPS.

**Figure 5: TPIMS Dynamic Messaging Signs**

*Roadside signs will display real-time parking information because the actual number of available spots may change by the time a driver reaches the reported facility. To minimize this being an issue, roadside signs and data streams will be required to refresh at a rate of no less than one time every five minutes; and, DTSPS design requirements recommend signs be placed at a maximum distance of 60 miles from the next truck parking facility so that drivers can make efficient, timely*

26 parties, the interface and how the truck drivers receive the data will be primarily left to developers and  
27 how they interface with their customers (mobile application, fleet logistics partners, on-board telematics  
28 providers, etc.). Regulations prohibit drivers from using hand-held devices while in-route, so third-party

The intent is to enable a truck driver to evaluate whether to stop at the next available facility or continue to another facility where more parking may be available or could get them further towards their destination within their legal hours of service.

Additionally, when parking facilities begin to reach capacity the number of available spaces tends to be volatile, and some lots accommodate informal parking beyond the striped parking spaces. Therefore, the MAASTO TPIMS Partnership has agreed to display the word “LOW” on signs and within data streams when the calculated availability drops below a pre-determined threshold. Due to the differing technology preferences and number of spots available per site, each agency determines what the threshold for “LOW” will be at each of its sites.

Websites and mobile applications - official agency-supported platforms like 511 as well as third-party platforms – also will be options. For data shared through third-

**Figure 6: Lesson 3**

### COMMUNICATE EARLY AND OFTEN

Team members may differ regarding the manner of system design and testing. But common standards for testing and communication increase the likelihood of success. Early in TPIMS design, for example, it became clear that moving parking facility utilities could require more coordination than expected. Sharing this enabled agency partners to adapt construction and testing approaches, eliminating potential delay. For TPIMS, as each state was completing final design and installation prior to testing, monthly project team meetings coupled with individual WebEx conference calls combined to make sure that work was proceeding on schedule and that partner agencies could benefit from each other’s experiences.

1 vendors and commercial fleets will be tasked with finding a way to integrate TPIMS data with the hands-  
2 free technologies currently used for fuel efficiency, supply chain management, and driver logging.

### 3 **Evolution of TPIMS regional collaboration**

4 Members of the TPIMS Partnership originally came together to make it easier for truck drivers to reliably  
5 find safe places to park through use ITS technology. The system they envisioned would be designed to  
6 provide over-the-road truck operators with accurate, actionable truck parking information that would save  
7 them from wasting their limited legal hours of service searching for places to park for their Federal Motor  
8 Carrier Safety Administration mandated rest periods (6) or from using unsafe informal or illegal parking  
9 locations, jeopardizing their safety and that of  
10 other motorists on the roads they share.

**Figure 7: Lesson 4**

11 What is pioneering about TPIMS is that state  
12 agencies have collaborated to ensure that the  
13 truck parking system on an interstate corridor  
14 does not stop at the state boundary. Each of  
15 TPIMS Partnership states recognized that the  
16 need for a truck parking system is not simply a  
17 state issue, but a regional issue, as drivers can  
18 cover up to 600 miles of roadway in one shift.

19 There was also the realization that addressing  
20 this issue would require ensuring that each  
21 agency had the flexibility to work out for itself  
22 the technical details of its state truck parking  
23 system - with the understanding that the overall  
24 system must appear seamless to the truck  
25 operator when moving from state to state and  
26 must adhere to the same levels of performance.

27 TIGER grants require demonstrating close adherence to budget and schedule requirements. This put a  
28 premium on clearly defining roles and expectations to avoid unanticipated delays or budget risks that  
29 might arise from developing an architecture flexible enough for each state to create an individual parking  
30 information system integrated into its existing ITS network and software platform - yet still capable of  
31 regional interoperability.

32 In this environment, each state committed to its own implementation budget and schedule that supported  
33 those of the overall project. Three partner states that had begun deploying precursor TPIMS projects  
34 served as technical resources. The Mid-America Freight Coalition was brought on board to serve as the  
35 project's data warehouse and to assess performance after the system goes live.

#### **DEFINE ROLES CLEARLY**

As the lead applicant for this project, KDOT administers the TIGER grant; manages the group's activities in support of monthly and milestone progress; and facilitates group and stakeholder meetings designed to ensure that the system meets partner and end-user needs and expectations. This frees up each state to focus on only its own implementation plan, schedule and budget.

1 So far, this approach has worked smoothly and efficiently as evidenced by the fact that the original \$25  
2 million TIGER grant has grown to a total of nearly \$35 million in additional state and federal funding.  
3 The project has moved on to Phase Two (Final Design and  
4 Deployment) after successfully completing Phase One in  
5 the 4Q of 2016 (Concept of Operations and 30%  
6 Design). The system-wide go-live date of January 4,  
7 2019 still holds.

8 With full implementation, the use of ITS technology in  
9 TPIMS is expected to significantly reduce the amount of  
10 fatigue-related accidents that occur on interstates every  
11 year. In the three years after system launch, the system  
12 will be evaluated to determine if the performance  
13 measures are being met and if truck operators are  
14 reporting a positive experience using the system.  
15

16 And ultimately, the MAASTO TPIMS Partnership will  
17 strengthen America’s freight network by helping  
18 commercial truckers make safer, more efficient parking  
19 decisions through a user-focused information service that consistently provides timely, reliable parking  
20 availability information. The MAASTO TPIMS initiative will provide a truly regional ITS-driven system  
21 within which truck drivers, dispatchers and others will see a consistent, cohesive parking availability  
22 system regardless of when or where they cross state lines.

**Figure 8: Other Success Factors**

- Verify proposed sign locations to preclude field issues.
- Locate signs to maximize truck driver decision making.
- Market new system internally and externally to maximize acceptance and use.
- Coordinate with other current and proposed truck parking system to ensure consistent regional and national protocols for information distribution.

1 **AUTHOR CONTRIBUTION STATEMENT**

2 The authors confirm contribution to the paper as follows: project conception and design: Davonna Moore,  
3 Gretchen Ivy, Brian Comer, Michael DeMent, Matthew Junak, and Charles Miller. The same individuals  
4 participated in the preparation and review of the manuscript and approve the final version of the  
5 manuscript.

**Reviewer Comments Matrix**

"Creating a roadmap for successfully planning, implementing and administering complex multi-jurisdictional transportation technology projects."

<b>Reviewer</b>	<b>Location</b>	<b>Subject</b>	<b>Reviewer Comment</b>	<b>Response</b>
Reviewer #2	Page 1	Edit	"Iowa is duplicated in the abstract."	Deleted.
Reviewer #2	Throughout	General	"The lessons learned while inverting and should be included don't seem to follow standard TRB processes for research/informational papers. This is more informative than research but it will be interesting to hear the report out in a couple of years for how this partnership is working and if there is a measurable reduction in fatigue related incidents in the trucking industry in these areas."	Noted. No changes to the document were made at this time.
Reviewer #2	Throughout	Format	"There are some formatting issues happening in the paper especially the page with figure 3."	Formatting has been fixed.
Reviewer #3	Throughout	Format	"Lessons Learned graphics are not numbered. They look fine in the paper but cannot be referenced."	Formatting has been fixed.
Reviewer #4	Page 2	Text	"The paper certainly delivers on the title. The weaving of the Lessons Learned and Other Success Factors is nicely done - speaks to the ITS systems engineering philosophy. Certainly not needed or wanted to get into a discussion of ITS systems engineering. Was great to see the authors hit a lot of the ITS systems engineering boxes without getting into the systems engineering jargon. Still, but might be worthwhile to mention it in the first part of the paper if indeed ITS systems engineering was used."	Noted. A short paragraph has been added in the introduction that explicitly confirms the systems engineering process was followed.
Reviewer #4	Throughout	Format	"Other than the comments on Table 1, and Figure 2, I do not have any recommendations for improvement."	Formatting has been fixed.
